

Efficiently Inferring Non-hierarchical Structure in Parsing and Computation

Danny McClanahan

2021-06-20

Abstract: This paper proposes to revise the general definition of a “grammar”¹ as well as “parsing”². A meta-language named “Simultaneous Productions” (or “S.P”) is proposed for specifying a parseable grammar (similar in intent to EBNF³). This meta-language is shown to be able to represent recursively enumerable languages⁴, and several favorable properties of this meta-language across various parsing use cases are discussed.

An actual “evaluation method” (or “parsing algorithm”) is then introduced for the proposed S.P. grammar model, which shares some similarities with the CYK algorithm⁵. This method is shown to terminate in $\mathcal{O}(n^3)$ time across $\mathcal{O}(n)$ inputs. This method is then demonstrated to have the peculiar property of directly parameterizing context-sensitivity⁸. The practical and theoretical ramifications of this result are discussed and speculated on.

This paper will frequently refer to free software provided at [1] which implements all of the theoretical mechanisms discussed.

1 Motivation

2 Meta-Language for Grammar Specification

3 Fully General Parse Method

4 Re-parameterization of the Chomsky Hierarchy

TODO:

- describe the hierarchy as being better described by derivatives (?) of a function corresponding to stack depth (!!!) and link it to approximation difficulty!¹⁰
 - *the important link here is between the # of derivatives required to approximate the function and the taylor series!*
- make S.P. support multiple parallel stacks, then reduce (2) to a k -stack automaton (equivalent to a T.M.)¹¹
